Introduction

Air pollution harms human health and the environment. In Europe, emissions of many air pollutants have decreased substantially in recent decades, resulting in improved air quality across the region. However, air pollutant concentrations are still too high, and air quality problems persist.

This fact sheet presents compiled information based on the latest official air pollution data reported by the European Environment Agency's (EEA) member

countries. A comprehensive overview of information about Europe's air quality is also published each year by the EEA in the report '[Air quality in Europe](#)'. A number of other [publications addressing air pollution](#) are also published by the EEA each year. Information on the data sources used is provided at the back of this fact sheet, together with a glossary explaining the various abbreviations and acronyms used throughout.

Air pollutant emissions and projections

Air pollutants are emitted from a range of both man-made and natural sources including:

- burning of fossil fuels in electricity generation, transport, industry, and households;
- industrial processes and solvent use, for example in the chemical and mining industries;
- agriculture;
- waste treatment;
- natural sources, including volcanic eruptions, windblown dust, sea-salt spray and emissions of volatile organic compounds from plants.

For EU Member States, the [National Emission Ceilings Directive](#) (NEC Directive) sets emission ceilings (or limits) for the year 2010 and thereafter for man-made emissions of four key air pollutants (nitrogen oxides, sulphur dioxide, non-methane volatile organic compounds, and ammonia). These pollutants harm human health and the environment. Information concerning the revision of the NEC Directive is available on the website of the

European Commission's DG Environment [here](#). Internationally, the issue of air pollution emissions is also addressed by the [UNECE Convention on Long-range Transboundary Air Pollution](#) (the LRTAP Convention) and its [protocols](#). The [Gothenburg 'multi-pollutant' protocol](#) under the LRTAP Convention was amended in May 2012. In addition to emission ceilings for 2010 (that for the EU Member States, are either equal to or less ambitious than those in the EU NEC Directive), the revised protocol now includes emission reduction commitments for 2020 expressed as a percentage of 2005 emissions. The revised Protocol also introduced a 2020 emission reduction commitment for PM_{2.5}.

The following section shows information on the past emission trends of key air pollutants. It also compares the latest reported data with respective national ceiling limits and, shows (where this information is available) information on the expected level of future emissions.

Box 1. Facts about air pollutants

Pollutant	Description and sources	Health and environment effects
Sulphur dioxide (SO₂)	SO ₂ is formed by oxidation of sulphur (S), mainly through combustion of fuels containing S. The electricity generation sector is the most important source of SO ₂ . SO ₂ also can contribute to the formation of secondary sulphate particles in the atmosphere.	SO ₂ aggravates asthma and can reduce lung function and inflame the respiratory tract. It can cause headache, general discomfort and anxiety. SO ₂ contributes to acid deposition, the impacts of which can be significant, causing damage to forests and ecosystems in rivers and lakes.
Nitrogen oxides (NO_x)	NO _x is emitted during fuel combustion e.g. from industrial facilities and the road transport sector. NO _x is a group of gases comprising nitrogen monoxide (NO) and nitrogen dioxide (NO ₂). NO makes up the majority of NO _x emissions. NO _x contributes to the formation of ozone and particulate matter.	NO ₂ is associated with adverse effects on health: it can affect the liver, lung, spleen and blood. It can also aggravate lung diseases leading to respiratory symptoms and increased susceptibility to respiratory infection. As with SO ₂ , NO _x contributes to acid deposition but also to eutrophication of soil and water.
Particulate matter (PM)	PM is a mixture of aerosol particles (solid and liquid) covering a wide range of sizes and chemical compositions. PM ₁₀ (PM _{2.5}) refers to particles with a diameter of 10 (2.5) micrometres or less. PM is either directly emitted as primary particles or it forms in the atmosphere from emissions of SO ₂ , NO _x , NH ₃ and NMVOCs. PM is emitted from many anthropogenic sources, including both combustion and non-combustion sources. Important natural sources of PM are sea salt and natural re-suspended dust.	PM can cause or aggravate cardiovascular and lung diseases, heart attacks and arrhythmias. It can also affect the central nervous system and the reproductive system, and can cause cancer. One outcome of exposure to PM can be premature death. PM also acts as a greenhouse gas, mainly cooling the earth's climate, although in some cases it can lead to warming. PM in the atmosphere can also alter rainfall patterns, and affect the surface albedo properties of snow (the extent to which the snow reflects light).
Ozone (O₃)	Ground-level (tropospheric) ozone is not directly emitted into the atmosphere. Instead, it forms in the atmosphere from a chain of chemical reactions following emissions of certain precursor gases: NO _x , carbon monoxide (CO) and NMVOCs and methane (CH ₄).	Elevated levels of ozone can cause respiratory health problems, including decreased lung function, aggravation of asthma, and other lung diseases. It can also lead to premature mortality. Ozone is also a greenhouse gas contributing to warming of the atmosphere.
Ammonia (NH₃)	The vast majority of NH ₃ emissions come from the agricultural sector, in connection with activities such as manure storage, slurry spreading, and the use of synthetic nitrogenous fertilisers. It also contributes to the formation of secondary particles.	Exposure to high levels of ammonia may irritate skin, eyes, throat, and lungs and cause coughing. People with asthma may be more sensitive to breathing ammonia than others. NH ₃ , like NO _x , contributes to eutrophication and acidification.
Non methane volatile organic compounds (NMVOCs)	NMVOCs produce photochemical oxidants by reacting with NO _x in the presence of sunlight. Anthropogenic NMVOCs are emitted from sources including paint application, road transport, dry-cleaning and other solvent uses. Biogenic NMVOCs are emitted by vegetation, with the amounts emitted dependent on species and on temperature.	NMVOCs include a variety of chemicals. Certain NMVOC species, such as benzene (C ₆ H ₆) and 1,3-butadiene, are directly hazardous to human health. NMVOCs are also precursors of ground-level ozone.
Carbon monoxide (CO)	CO is emitted due to incomplete combustion. Important sources of CO include road transport, businesses, households, and industry. CO reacts with other pollutants producing ground-level ozone.	CO can lead to heart disease and damage to the nervous system. It can also cause headache, dizziness and fatigue.
Methane (CH₄)	CH ₄ is produced by both anthropogenic and natural sources. Significant anthropogenic sources include the agriculture sector (from the enteric fermentation of CH ₄ from livestock), the waste sector, and 'fugitive' emissions from coal mining and gas.	Methane is an important greenhouse gas, and is one of the gases controlled under the UNFCCC's Kyoto protocol. At the regional and global scale methane also contributes to the formation of ground level ozone.

Progress towards ceilings	Current and projected progress towards ceilings		Value	Unit
	2010 NECD emission ceiling for NO _x		61	(Gg)

Linking air emissions and air quality

Emissions of the main air pollutants in Europe have declined since 1990. Over the past decade, this reduction in emissions has resulted – for some of the pollutants – in improved air quality across the region. However, due to the complex links between emissions and air quality, emission reductions do not always produce a corresponding drop in atmospheric concentrations, especially for PM and O₃.

For example, while reductions of O₃-forming substances (i.e. O₃ precursor gases) have been substantial in Europe, O₃ concentrations in Europe have remained stable. Concentration levels depend on year-by-year variations in weather conditions including sunlight; natural emissions of ozone

precursor substances by vegetation; the increase in global background ozone concentrations; and transportation of ozone and of ozone precursor substances from source areas outside Europe. All these contributing factors mean that European emission reductions of pollutants contributing to the formation of ozone may not result in equivalent reductions of ozone concentrations.

Improving our understanding of air pollution therefore remains a challenge. Developing and implementing effective policy to reduce air pollution should be a priority. For further information, see the EEA annual report [Air quality in Europe](#).

Exposure of urban population to selected air pollutants

Exposure of urban population ⁽¹⁾

Percentage of the urban population exposed to air pollutant concentrations above the EU air quality objectives (2009-2011) ⁽²⁾

Latvia	EU reference value	Exposure estimate (%) (minimum and maximum over the period)	
PM ₁₀	day (50 µg/m ³)	0	
O ₃	8-hour (120 µg/m ³)	0	
NO ₂	year (40 µg/m ³)	0	

The colour coding of exposure estimates refers to the fraction of urban population exposed to concentrations above the reference level:

< 5 %	5-50 %	50-75 %	> 75 %
-------	--------	---------	--------

⁽¹⁾ The detailed methodology of the calculation can be found at:

<http://www.eea.europa.eu/data-and-maps/indicators/exceedance-of-air-quality-limit-1/>

⁽²⁾ The pollutants in this table are ordered in terms of their relative risk for health damage. The reference levels include EU limit or target values. For PM₁₀ and NO₂ the estimates are related to the most stringent EU limit value set for the protection of human health. For O₃ there is only one target value.

Trends of exposure of urban population

Percentage of the urban population potentially exposed to air pollution exceeding EU air quality objectives (the most stringent EU limit values for PM₁₀ and NO₂ and the target value for O₃ set for the protection of human health have been chosen)

This indicator has been estimated to be '0' for the period of the trend analysis (2002-2011).

Trends of exposure of total population

Percentage of the total population exposed to PM₁₀ concentrations above the limit values (LV) and the population-weighted concentration for the human health PM₁₀ indicators annual average and 36th maximum daily average for 2006 to 2010 ⁽³⁾

Latvia PM ₁₀	2006	2007	2008	2009	2010
Annual average					
Population-weighted concentration (µg/m ³)	21.9	17.8	19.1	18.8	21.5
Population exposed > ALV (%)	0	0	0	0	0
36th maximum daily average					
Population-weighted concentration (µg/m ³)	40.0	31.9	32.7	33.4	37.8
Population exposed > DLV (%)	0	0	0	0	0

Percentage of the total population exposed to ozone concentrations above the target value (TV) for the 26th highest daily maximum 8-hour average; and the population-weighted concentrations for 2006 to 2010

Latvia ozone	2006	2007	2008	2009	2010
26th highest daily maximum 8-hr. average					
Population-weighted concentration (µg/m ³)	103.8	95.8	94.9	91.9	92.8
Population exposed > TV (%)	0	0	0	0	0

⁽³⁾ The methodology to calculate concentrations can be found at:

http://acm.eionet.europa.eu/reports/docs/ETCACM_TP_2012_12_AQMaps2010.pdf

Air quality status

The calculations for the attainment status presented below have been made for stations with a data capture of at least 75 % per calendar year.

Nitrogen dioxide (NO₂)

NO₂ monitoring stations in the EEA's air quality database – AirBase (year 2011)

Station classification	Number of stations	Percentage
Other	0	0.0
Rural	1	11.1
Traffic	5	55.6
Urban	3	33.3
Total	9	100.0

Location, type and number of stations for which 2011 air quality data for nitrogen dioxide have been reported

- Urban (3)
- Traffic (5)
- Rural (1)
- Other (0)

Directive 2008/50/EC annual limit value (ALV): 40 µg/m³

NO₂ ALV attainment status at monitoring stations (year 2011)

Station classification	Number of stations	Number of stations in non-attainment of ALV	Percentage of stations in non-attainment of ALV (percentage of total)	Percentage of stations in non-attainment of ALV (percentage of station type)
Other	0	0	0.0	0.0
Rural	1	0	0.0	0.0
Traffic	3	1	14.3	33.3
Urban	3	0	0.0	0.0
Total	7	1	14.3	-

Annual mean nitrogen dioxide 2011 and number of stations, based on daily averages with percentage of valid measurements ≥ 75% in µg/m³

- ≤ 20 (2)
- 20-30 (4)
- 30-40 (0)
- 40-50 (1)
- > 50 (0)

Directive 2008/50/EC hourly limit value (HLV): 200 $\mu\text{g}/\text{m}^3$, not to be exceeded more than 18 times

NO₂ HLV attainment status at monitoring stations (year 2011)

Station classification	Number of stations	Number of stations in non-attainment of HLV	Percentage of stations in non-attainment of HLV (percentage of total)	Percentage of stations in non-attainment of HLV (percentage of station type)
Other	0	0	0.0	0.0
Rural	0	0	0.0	0.0

Changes in concentrations and impacts of air pollutants caused by emissions from other countries

Source-receptor (SR) relationships are a type of data developed by the Cooperative Programme for Monitoring and Evaluation of the Long-range Transmission of Air Pollutants in Europe (EMEP). SRs provide information on the change in air concentrations, deposition or impacts that arise from changes in emissions from different emitting countries.

Each figure which follows provides an indication of the distribution of imported air pollution by country. Results are dependent upon the version of the EMEP model being used, the absolute magnitude of emissions, and meteorological drivers.

The charts below show the source-receptor relationships for each country for three selected parameters:

- Ground-level mean ozone over 35 ppb (SOMO35) (effect of a 15% reduction in precursor NO_x emissions);
- Ground-level mean ozone over 35 ppb (SOMO35) (effect of a 15% reduction in precursor NMVOC emissions);
- PM_{2.5}. Effect on PM_{2.5} concentrations caused by a 15% reduction in all precursor emissions (i.e. primary PM_{2.5}, SO_x, NO_x, NH₃ and VOC).

Further information on the source-receptor matrices is available from the [EMEP website](#).

The six most important emitter countries, or regions, with respect to the reduction in SOMO35 in Latvia that would result from a 15 % decrease in NO_x emissions

Source: EMEP/MSC-W

Note: BIC – Boundary and Initial Conditions; RUE – Russian Federation (extended EMEP domain); ATL – Remaining N.E. Atlantic

The six most important emitter countries, or regions, with respect to the reduction in SOMO35 in Latvia that would result from a 15 % decrease in NMVOC emissions

Source: EMEP/MSC-W

Background

Air pollution is a complex problem. Different pollutants interact in the atmosphere, affecting our health, environment and climate.

Air pollutants are emitted from almost all economic and societal activities. Across Europe as a whole, emissions of many air pollutants have decreased in recent decades, and much progress has been made in tackling air pollutants such as sulphur dioxide (SO₂), carbon monoxide (CO) and benzene (C₆H₆). However, air pollutant concentrations are still too high and harm our health and the ecosystems we depend on. A significant proportion of Europe's population lives in areas – especially cities –

where exceedances of air quality standards occur. Particulate matter (PM) and ozone (O₃) pollution are particularly associated with serious health risks.

Air pollutants released in one European country may contribute to or result in poor air quality elsewhere. Moreover, important contributions from intercontinental transport influence O₃ and PM concentrations in Europe. Addressing air pollution requires local measures to improve air quality, greater international cooperation, and a focus on the links between climate policies and air pollution policies.

Note: From left to right the pollutants shown are as follows: sulphur dioxide (SO₂), nitrogen oxides (NO_x), carbon monoxide (CO), ammonia (NH₃), particulate matter (PM), non-methane volatile organic compounds (NMVOC), polycyclic aromatic hydrocarbons (PAH), methane (CH₄), heavy metals (HM).

Further information and data sources

Data sources

Air quality concentration data are from [AirBase v. 7](#), the EEA's public air quality database, which stores data reported by EEA member countries. Concentration data measured in the year 'x' are submitted by 30 September of the following year (x+1) and become publicly available in Airbase by March of year x+2. These data correspond to measurements taken at air quality monitoring stations. Stations are defined according to the type of area they represent and the dominant emission sources in that area.

Station types include:

- **rural stations** located outside of built-up urban areas;
- **urban stations** located in built-up areas where pollution levels are not influenced significantly by any single source or street, but rather by a combination of many sources;
- **traffic stations** located such that the pollution levels they record are determined predominantly by the emissions from nearby traffic; and
- **other stations**, mainly industrial stations, located such that the pollution levels they record are influenced predominantly by emissions from nearby single industrial sources or by emissions from industrial areas with many pollution sources.

European legislation establishes [air quality objectives \(limit and target values\)](#) for the different pollutants. These are concentrations that must not be exceeded in a given period of time.

The estimations of the population exposure were obtained from the EEA's [Core Set Indicator 004 and from interpolated AQ maps](#).

Estimated emissions of air pollutants 1990-2011 and projections data are from the annual [European Union emission inventory submitted under the UNECE Convention on Long-range Transboundary Air Pollution \(LRTAP\)](#), and [data submitted under the EU National Emission Ceilings Directive \(81/2001/EC\)](#). Emissions data for some countries is gap-filled – further details are contained in the [annual EU emission inventory report submitted to the LRTAP Convention](#). Methane data is from GHG data reported under the EU GHG Monitoring Mechanism (280/2004/EC)/UNFCCC.

The 'with measures' projections illustrated refer to projections of anthropogenic emissions that encompass the effects, in terms of air pollutant emission reductions, of policies and measures that have been adopted at the time the projection is calculated.

Information on [source-receptor relationships](#) was obtained from EMEP for the year 2010 (website accessed 20 June 2013).

Units, abbreviations and acronyms

ALV	Annual limit value	NEC Directive	EU National Emission Ceilings Directive (2001/81/EC)
BaP	Benzo(a)pyrene	NH ₃	Ammonia
C ₆ H ₆	Benzene	NMVOC(s)	Non-methane volatile organic compound(s)
CH ₄	Methane	NO ₂	Nitrogen dioxide
CO	Carbon monoxide	NO _x	Nitrogen oxides
DLV	Daily limit value	O ₃	Ozone
EEA	European Environment Agency	PAH(s)	Polycyclic aromatic hydrocarbon(s)
Eionet	European Environment Information and Observation Network	PM	Particulate matter
EMEP	European Monitoring and Evaluation Programme (Cooperative programme for monitoring and evaluation of the long-range transmissions of air pollutants in Europe)	PM ₁₀	Coarse particulate matter (particles measuring 10 µm or less)
ETC/ACM	European Topic Centre on Air Pollution and Climate Change Mitigation of the EEA	PM _{2.5}	Fine particulate matter (particles measuring 2.5 µm or less)
EU	European Union	SO ₂	Sulphur dioxide
Gg	1 gigagram = 10 ⁹ g = 1 kilotonne (kt)	SO _x	Sulphur oxides
GHG	Greenhouse gas	SOMO35	The sum of the amounts by which maximum daily 8-hour concentrations of ozone exceed 70 µg m ⁻³ (cut-off value) on each day in a calendar year.
GP	Gothenburg Protocol of the LRTAP Convention	SR	Source-receptor relationships
HLV	Hourly limit value	t	1 tonne (metric) = 1 megagram (Mg) = 10 ⁶ g
kg	1 kilogram = 10 ³ g (gram)	TV	Target value
LRTAP	Long-range Transboundary Air Pollution (Convention)	TVt	Target value threshold
LTO	Long-term objective	µg/m ³	micrograms per cubic meter
LV	Limit value	UNECE	United Nations Economic Commission for Europe
n/a	Not applicable/not available	VOC(s)	Volatile organic compound(s)
